#1

Neural Probability Channel Upper study, Lower study, MTF version study and Watchlist column.

I added clouds, candle color, dark gray inner lines, and divergence for both. This is a 2-hour chart of /NQ.

Original code can be found here.

<https://www.tradingview.com/script/mFj3oD5h-Neural-Probability-Channel-AlgoPoint/>

The Neural Probability Channel (NPC) is a next-generation volatility and trend analysis tool designed to overcome the limitations of traditional bands (like Bollinger Bands) and smoothing filters (like standard Moving Averages).

Unlike traditional indicators that rely on linear deviation or simple averages, the NPC utilizes a Rational Quadratic Kernel—a concept derived from machine learning regression models—to calculate a non-repainting, highly adaptive baseline (Fair Value). This allows the indicator to distinguish between market noise and genuine trend shifts with superior accuracy.

The volatility bands are dynamically calculated using a hybrid of Standard Error (Mean Deviation) and ATR, ensuring the channels adapt organically to market conditions—expanding during high-impact moves and contracting during consolidation.

How It Works

- The Neural Baseline (Center Line): Instead of a standard Moving Average, the NPC uses a Rational Quadratic Kernel weighting system. This assigns "importance" to price data based on both recency and similarity. It acts as a "Center of Gravity" for price, providing a smoother yet responsive trend detection line without the lag associated with SMAs or EMAs. Crucially, the math is causal (no lookahead), meaning it does not repaint.

- Adaptive Volatility Bands: The channel width is not fixed. It uses a Hybrid Volatility Model:
- Inner Channel: Represents the "Probability Zone" (approx. 70% confidence). Price staying here indicates a stable trend.

- **Outer Channel:** Represents "Extreme Deviation" (Statistical Anomalies). When price touches or breaches these outer bands, it is statistically overextended (Overbought/Oversold).

Signal Generation:

- **Reversion Signals:** Generated when price breaches the Outer Bands and closes back inside. This suggests a "Snap-back" or Mean Reversion event.
- **Trend Confirmation:** The color of the baseline and the fill zones changes based on the slope of the Kernel, giving an instant visual read on market bias.

How to Use It

- **Mean Reversion Strategy:** Look for price action extending beyond the Outer Bands (Thinner lines). If price leaves a wick and closes back inside, it signals a high-probability reversal toward the Neural Baseline.
- **Green Signal:** Potential Long (Reversal from Lows).
- **Red Signal:** Potential Short (Reversal from Highs).
- **Trend Following:** Use the Neural Baseline (Thick Center Line) as a dynamic support/resistance level.

If price is holding above the baseline and the cloud is green, the trend is Bullish.

If price is holding below the baseline and the cloud is red, the trend is Bearish.

- **Squeeze Detection:** When the Inner and Outer bands compress significantly, it indicates low volatility and often precedes an explosive breakout.

@chewie76

Damn, this even looks pretty! Is it possible to share your full TOS link so that we have the indicators and styles intact? For both normal and MTF? Seriously this looks amazing and easy on the eyes! Thank you!

What time frame for the watchlist?

You can change the time frame to whatever you like depending on your strategy. If you are swing trading, the 4hr, 2hr or 1hr are good fits. Test it out yourself, look at different timeframes, and you decide which one performs better for you.

Just add this to the bottom.

Alert(bullish, "Bull Div", Alert.BAR, Sound.Bell);

Alert(bearish, "Bear Div", Alert.BAR, Sound.Bell);

This is great but it doesn't have your style setup just the indicator studies, which is good too. Thank you again!
